ABSTRACT

An analysis was done of the quality of the data supplied by respondents to the National Postsecondary Student Aid Study, 1987 (NPSAS:87). The NPSAS:87 was a large-scale survey that obtained extensive data on the educational, demographic, and financial aspects of postsecondary students and their parents. The study compared the responses to similar questions asked of the three groups of respondents to determine the consistency and validity of responses. In particular comparisons were made for similar items between students and institutions, between parents and institutions, and between parents and students. The analysis found the following: (1) good correspondence was found between student and institution respondents for factual demographic information such as student age, sex, year of high school degree and marital status; (2) there was little agreement between students and institutions with regard to whether or not students received certain types of financial aid with students tending to underreport amount of aid received; (3) there was good agreement between parents and institutions for reporting adjusted gross income; (4) parents were not as accurate in reporting on tuition and fees as institutions and parents systematically overreported the amount paid for tuition and fees. Appendixes contain methodology and technical information. (JB)

Foreword

This report uses information about students, parents, and institutions from the National Postsecondary Student Aid Study, 1987 (NPSAS:87). The information analyzed ranges from the demographic data about the students and parents to the financial aid received by the student from the institution. The report compares the responses to similar questions asked of the three groups of respondents to determine the consistency and validity of responses.

NPSAS:87 is a large-scale survey that contains extensive information on the education, demographic, and financial aspects of postsecondary education of students and their parents. The survey is representative of both graduate and undergraduate students who attend all sectors of postsecondary institutions. The financial aid information collected in the survey is of particular importance since the process of awarding financial aid by institutions and the method by which students finance their education are complex.

The purpose of this report is to provide a broad look at the quality of the data supplied by different respondents. The report is not the definitive analysis of these data. It is hoped that other researchers will use the results from this report to further explore the issues of data quality.

Information about obtaining the NPSAS data file is available from the U.S. Department of Education, Office of Educational Research and Improvement, Information Technology Branch, 555 New Jersey Avenue, N.W., Room 215, Capitol Place Building, Washington, D.C. 20208.

Acknowledgments

The author wishes to thank all those persons who contributed to the production of this report, particularly Laura Horn. Kieri Custodio, Ramona McCowan, and Sharlene Mulder produced and formatted the tables.

Thanks also to Bob Burton of the NCES, who provided very helpful comments on an early draft of the report. We would also like to acknowledge the panel of reviewers who read the report: Roz Korb, Steven Kaufman, and Andy Kolstad of NCES, and Tim Christensen of the National Association of Student Financial Aid Administrators.

Special thanks go to C. Dennis Carroll and Carl M. Schmitt of the Longitudinal Studies Branch for their comments and suggestions throughout the life of this task.

Highlights

This report examines the quality of responses to the 1986-87 National Postsecondary Student Aid Study survey. Three sets of comparisons were made for similar items asked in the survey: between students and institutions, between parents and institutions, and between parents and students. Items that were compared include demographic characteristics, family financial characteristics, and financial aid information. Correspondence was measured using two correlation methods. Pearson's product moment correlation was employed for variables measured on an interval or ordinal scale such as parents' education; and Cramer's V was used for variables measured on a nominal scale such as race-ethnicity. Whether or not there was a systematic bias in reporting dollar amounts was also examined. A few of the major highlights are as follows:

Student-Institution Comparisons

- Good correspondence was found between student and institution responses for factual demographic information such as student's age, sex, year of high school degree and marital status (correlation coefficients ranging from .81 to .97). Agreement was slightly lower for race-ethnicity (correlation = .75).
- There was little agreement between students and institutions with regard to whether or not students received certain types of financial aid (mean correlation for receipt of grant aid, work aid, loan aid, and federal aid = .14).
- Somewhat better correspondence was found for the actual amounts of aid received, though agreement was still relatively low (.38). The best agreement was found for the amount of loan aid received (.52).
- Compared to institution records, students systematically underreported the amounts of financial aid they received: by 16 percent for loan aid, 32 percent for grant aid, and 76 percent for work aid.
- Students were somewhat more reliable in reporting family financial characteristics such as income and federal income tax paid (average correlation = .63).

Parent-Institution Comparisons

- There was relatively good agreement between parents and institutions for reporting adjusted gross income (.83), number of dependents (.79), and federal income taxes paid (.76).
- Parents were not as accurate in reporting on tuition and fees relative to the institution record (.65). Furthermore, parents systematically overreported the amount paid for tuition and fees.

Parent-Student Comparisons

- Students and parents were in relative agreement when reporting on parents'

highest education (.63 and .69, respectively, for mother's and father's education).

- While students and parents had moderate agreement for the amount paid for tuition and fees (.64), they had poor agreement for parent's income (.27) and for the amount of money parents lent to students (.17).
- There was better agreement between parents and students with respect to the amount of non-loan contributions parents made toward students' educational expenses (.54).
- Relative to their parents, students tended to overreport the amount of non-loan contributions made by their parents and underreport the amount of loans provided by parents.

Chapter 1

Introduction

The need for a comprehensive national database on postsecondary student financial aid prompted the U.S. Department of Education to conduct the 1987 National Postsecondary Student Aid Study (NPSAS:87).¹ NPSAS is a nationally representative survey of postsecondary students and the institutions they attend. It also includes a subsample of students' parents. NPSAS participants provided information on many aspects of students' educational experiences, including course loads, costs, and financial aid. In addition, NPSAS provides detailed information on the demographic and economic backgrounds of students and their parents. The primary objective of the survey was to gather data on students' attendance costs at postsecondary institutions and on how students and their parents finance these costs.

Earlier studies about student financial aid were often limited because the data were obtained from a single source of respondents or concerned only a single financial aid program. In order to obtain accurate and complete information on student participation in financial aid programs, especially among students participating in multiple financial aid programs, it is essential to collect information from a combination of sources including students, parents, and institutions.² Thus, NPSAS was conceived to provide the first such comprehensive and nationally representative student-level database on postsecondary financial aid.

This report presents results from an analysis of the NPSAS:87 survey data. Specifically, this study compares self-reported information provided by students and their parents with information obtained from the institution. Comparisons between student and parent responses to similar items are also examined. The data are assessed by determining how well the information from the three sources corresponds. This particular analysis was conducted without the use of weights associated with the data. It was designed to study whether or not specific questionnaire items obtained accurate information. Comparisons of responses were analyzed on the whole respondent population and by major subgroups of student respondents such as attendance status, dependency status, and institutional type.

This report is organized into five chapters. This introductory chapter provides an overview of earlier survey data assessment studies and their relation to NPSAS. Chapter 2 discusses the NPSAS data and the methodology used to assess the quality of responses. Chapter 3 presents the findings, comparing student and parent responses with data collected from the institutions, and shows the correspondence between the responses of students and their parents. Chapter 4 compares the characteristics of the NPSAS students with those of the college-enrolled sample of the Current Population Survey (CPS). Chapter 5 concludes the report with a summary and discussion of the results.

Overview

¹ For a detailed description of NPSAS, see U.S. Department of Education, National Center for Education Statistics, *Methodology Report for the National Postsecondary Student Aid Study, 1987*, NCES 90-309, (Washington, D.C.: March 1990).

² *Ibid.*, 1.

Most of the studies analyzing the accuracy of self-reported survey data focus on two measures of quality: the *validity* of the data in relation to some true value and the *reliability* of the reported data over time. The *validity coefficient*, therefore, is generally defined as the correlation between the reported data and the "true" value, while the *reliability coefficient* is defined as the correlation between two responses to the same item given by an individual at different times.³ These measures represent an ideal means of assessment. However, as is often the case, a "true" value does not exist to test the validity of responses. Therefore, when there is more than one group of respondents such as students and parents or, in the case of NPSAS, students, parents, and institutions, a way of assessing the validity of information is to assume that one source of information is accurate and to test the other source against the "correct" one. Although this method does not necessarily ascertain the true value of the information, it does determine whether answers by one type of respondent are consistent with those of another type.

Social scientists often rely on survey data to analyze social experiences. The accuracy of self-reported information obtained from these surveys, however, has often been called into question. Consequently, a substantial literature on the validity and reliability of self-reported survey data has been generated. Most studies have analyzed the accuracy of student responses concerning their school experiences and the socioeconomic characteristics of their family by comparing them with parent responses to similar items. For example, when comparing the responses of students surveyed in High School and Beyond (HS&B), Fetters et al. were able to measure both the reliability and the validity of the student-reported data.⁴ In general, the authors found that students reported factual items such as race-ethnicity and parents' educational level with relative accuracy. However, students tended to be less accurate when reporting more subjective information, such as mothers' expectations for educational achievement. One factual item that students seemed to have great difficulty in reporting accurately was family income. This has also been found by other researchers. For example, Kayser and Summers found that although high school students were accurate reporters of their parents' education, they were not good reporters of their father's income.⁵

The results found by Fetters et al. confirm those findings from additional studies on the validity of student reports of family characteristics. In particular, Cohen and Orum found that children as young as age 9 already have an accurate idea of their parents' education level and occupations.⁶ In studying the responses of sons concerning the educational attainment and occupations of their fathers, Borus and Nestel concluded that, on average, the children's responses were similar to those of their fathers.⁷ Researchers have identified a number of factors that influence the accuracy of student-reported information. These factors include the wording of questions, the specific type of information requested, and the characteristics of the responding students such as age, gender, and race-ethnicity. In general, studies have determined

⁷ M. Borus and G. Nestel, "Response Bias in Reports of Father's Education and Socioeconomic Status," *Journal of American Statistical Association* 68 (344) (December 1973): 818.

that older children respond to survey questions more accurately than do younger children. For example, Feters et al. found HS&B seniors provided more accurate answers than did sophomores. Kerchoff et al. found that the validity of responses increased with the age of the children responding. However, this study also showed that this age-related trend tended to flatten out by the ninth grade.

Students' gender and race-ethnicity have also been found to influence accuracy in reporting family-related information. Feters et al. found females to be slightly more accurate respondents than males and white students to be somewhat more accurate than black students. Kerchoff et al. found that among younger boys (in the 6th and 9th grades), white students tended to be more accurate respondents than black students, although this discrepancy diminished by the 12th grade.

The way in which questions are asked on a survey plays an important role in how accurately students respond to family-related questions. Specifically, Cohen and Orum discovered that children were able to identify their father's occupation more accurately when the question was open-ended than when the question provided categories from which to choose. Furthermore, this study also showed that questions with few categories resulted in greater response accuracy than questions with many categories, and that items with the option of "I don't know" were reported more accurately than those without such an option.

Finally, the most obvious factor affecting self-reported survey data is the type of information requested. Studies assessing the validity and reliability of self-reported data consistently show that factual information is much more accurately reported than more subjective information. Furthermore, questions that are personally sensitive tend to produce less accurate responses than those that are not. Of particular importance to NPSAS is the fact that among the studies cited in this discussion assessing students' ability to report family income, all found that students are not a good source of this information. This may be the combined result of income being a sensitive item to some students and parents not generally discussing family income with their children.

The students participating in the NPSAS survey were older than those in the surveys cited in this discussion and should be more accurate reporters of family income. However, with its focus primarily on the financial aspects of postsecondary education attendance, the NPSAS survey goes far beyond other education surveys in requesting financially related information. For example, the NPSAS:87 financial aid questions were detailed and often complex and, as reported in the findings of this study, proved to be problematic for many student respondents. The U.S. Department of Education has conducted studies demonstrating that there is often disagreement between the information that families provide on their financial aid applications and the values as reported on their tax returns.⁸

In particular, *Quality in the Pell Grant Delivery System, Volume I-Findings*, Contractor Report, under contract No. 300-80-0952.

Chapter 2

Data and Methodology

NPSAS:87 is a cross-sectional survey of a nationally representative sample of students enrolled in postsecondary education in the fall of 1986.⁹ The survey included more than 43,000 students enrolled in over 1,000 postsecondary institutions. The student file contains responses on students' demographic characteristics, their educational experiences and aspirations, the financial situation of both students and their parents, the costs of attending college, and all sources of financial aid. The institutional file contains information on student demographics, family finances, and financial aid. In addition, the parents of a subsample of 27,000 students were surveyed to collect information on educational costs and financing and on family financial, educational, and employment characteristics.¹⁰ Because institutional records do not include family financial information on students who do not receive financial aid, a major objective of the parent survey was to collect this information for students who were financially dependent on their parents but who did not receive financial aid.

Limitations of the Data

There are some factors specifically related to the NPSAS survey that may influence the results of this analysis and should be taken into account when interpreting the findings. These factors, described in greater detail below, include:

- the timing of data collection for the three components of the survey (i.e., institutions, students, and parents) and the effect of long-term recall;
- the complexity of information requested;
- the comparability of information requested from students, parents, and institutions; and
- the limited sample size for many comparisons.

Timing of Data Collection

There were three groups of respondents to the NPSAS:87 survey including institutions, students, and parents. Data were collected from each of these groups at different times. For example, student surveys were mailed in six waves from mid-March through June 1987. Many of the questions asked of the students referred to the fall of 1986. Thus, toward the end of the

⁹ For more information about the design and data collection procedures of the NPSAS:87 data file, see U.S. Department of Education, National Center for Education Statistics, *Methodology Report for the National Postsecondary Student Aid Study, 1987*, Contractor Report, NCES 90-309 (March, 1990).

¹⁰ Parents of financially independent students over 25 years old were not included in the sample.

school year, many students were asked to respond to events that took place at the beginning of the school year.

Institution data, on the other hand, were initially collected between December 1986 and March 1987.¹¹ Most importantly, however, since financial aid-related information often changes during the academic year, additional *updated* institution data were collected from August 1987 through December 1987. Therefore, information originally supplied to the institution by students and parents or information concerning the amount of financial aid the student received could have changed during the year.

Finally, the parent data were collected in two stages. The surveys were mailed in May, June, and July 1987. Subsequently, between August and December of the same year, parents who did not respond to the mailed survey were telephoned and administered a telephone version of the survey. Given these circumstances, recall may also have been a problem for the parents who were asked to provide information that could have been up to a year old.

Two potential problems arise in using the institution as the point of comparison for student- and parent-reported data. One is the timing itself, in which students and parents were asked to provide detailed financial information relating to a time several months prior to data collection. Second, the institution records were updated to more accurately reflect financial aid information and it is this updated information that constitutes the final institution record for each student.

Complexity of Information

The focus of the NPSAS survey is to provide answers to fundamental questions about student aid including the status of student participation, the impact of financial aid programs on student enrollment and progress, and the impact of changes in financial aid policies on students and program costs.¹² In order to collect comprehensive information on such a large scale, it was necessary to collect data not only from students, but also from the institutions they attended and from a sample of parents. Furthermore, the financial information requested in NPSAS was far more extensive than that reported in previous surveys.

As discussed in the introductory chapter, studies have shown that students (high school age or younger) have difficulty accurately reporting family income. While postsecondary students are older and presumably capable of more accurately reporting on family income, the items requested in NPSAS were far more complex and sometimes required long-term recall as well as financial statements and documentation. In addition, parents may still not discuss their family income even with college age students. Students were asked whether or not they received specific types of student aid such as grants, loans, work-study, fellowships, and so on; who awarded the financial aid (that is, the institution, the state, or the federal government); and the exact amount awarded for the school year. If the students did not have the documents and forms available to fill in this information, it is unlikely that they could accurately recall such detail several months later. In addition to financial aid information, students were also requested to itemize their average total monthly expenses and to further break-out the expenses related directly to their education.

¹¹ At this time the registrar data provided the information necessary to locate respondents for the student and parent surveys.

¹² NPSAS:87 *Methodology Report*, 1.

Comparability of Information Collected from Institutions, Students, and Parents

The purpose of collecting data from the three different sources in the NPSAS survey was to provide as complete a picture as possible of how both aided and nonaided students pay for their postsecondary education. By using several data sources, NPSAS collected information on groups that have been systematically excluded from previous studies, such as students who do not participate in financial aid programs. With NPSAS data, therefore, analysts can conduct more in-depth examinations of both the level of need among students and the sources of their educational financing than were possible with previous studies.

Among the three groups of respondents, postsecondary institutions are the best source of data for federal, state, and institutional financial aid awards.¹³ Institutions are also likely to be the most accurate source of information on the family finances of students who apply for financial aid because students who receive financial aid must provide the institution with detailed and often verified financial data. The student survey, on the other hand, was crucial for providing information on the financial characteristics of students who did not receive financial aid. Finally, the parent survey was necessary to collect information on financially dependent students who did not receive financial aid. The data collected from the three different sources were, therefore, designed to supplement each other. While some overlapping information was collected, which forms the basis for this analysis, the specific emphasis and wording of the data items were different for each source. (See Appendix D for data items with different wordings.)

Moreover, when there is overlapping information obtained from different types of respondents, just who should be considered the most accurate source of such information depends on what is requested. As discussed above, the institution should be the best source of financial aid information. However, for students not receiving financial aid and who are financially dependent on their parents, it would seem reasonable that parents, not students, would be the best source of family finance information. Students, on the other hand, regardless of their dependency status, might be the best reporters of living expenses and other costs of attending the institution. Consequently, there is no single "standard" group of respondents. Rather than trying to determine the "validity" of the data, this analysis was designed to assess the internal consistency of the NPSAS data reported by three groups of respondents.

Limited Sample Sizes for Comparisons

While about 43,000 students participated in the NPSAS survey, only students who received financial aid (approximately 26,000) had institution financial aid records. In addition, parents were surveyed for only a sample of students. Approximately 22,000 students were initially selected to have their parents surveyed. However, only 13,423 (58 percent) parents responded, among whom, about one-half responded by mail and the other half were contacted and interviewed by phone.¹⁴ The response rate of parents of independent students was particularly low. Many of the overlap items collected from the three sources were only relevant to specific subgroups of students. For example, comparisons regarding actual amounts of financial aid awarded can only be made for those receiving the specific types of aid. Thus, these comparisons were possible for approximately 10,000 students who reported receiving federal aid, about 9,000 students who reported receiving loans, and about the 3,000 students who reported receiving work aid (see table 2.1 for sample sizes for each comparison). Additionally, a number of the financial

¹³ Ibid., 4.

¹⁴ A major reason for parent nonresponse was incomplete address information so that all parents could not be properly located.

items supplied by the students such as personal income, federal taxes, and number of dependents were relevant only for financially independent students.

Finally, in addition to survey non-response, item non-response was a problem for some of the variables examined. This was especially true of the parent survey, in which 33 percent of parents did not report adjusted gross income and 44 percent did not report federal income taxes paid.

Methodology

Comparisons of Responses

To assess the internal consistency of the information furnished by the three groups of respondents in NPSAS—students, parents, and institutions—three comparisons were made:

- student responses and institution data;
- parent responses and institution data; and
- student and parent responses.

The variables compared in each analysis are listed in table 2.1. The student-institution comparisons include student characteristics; financial items such as income; and financial aid receipt and awards. When comparing student information with institutional records, it was assumed that with respect to student characteristics items, students and institutions reported information with equal accuracy. However, with respect to information on financial aid, it was assumed that the institutional records were more accurate.

Five comparisons of parent responses with institutional data were possible using the NPSAS data. These included number of dependents, number of dependents in college, parents' adjusted gross income (AGI), federal income tax, and tuition and fees. It was assumed that both groups would provide equally accurate information about the number of dependents. For variables regarding the financial aspects of the family, however, it was assumed the institutions' records were more accurate since this information is used for awarding financial aid and therefore must be verifiable.

Table 2.1—NPSAS:87 variables used for analyzing the quality of responses

Student—Institution Comparisons		Included¹	N
<i>Student characteristics (all students)</i>			
Age	A		41,776
Sex	A		43,037

¹ A=all students, D=dependent students, I=independent students, F=received any financial aid, P=parents responded.

² Number of student—institution pairs where at least one respondent reported receipt of financial aid.

³ Number of students receiving specific financial aid and who reported amount.

The final set of comparisons, between students and parents, is more typical of previous analyses that assessed the quality of self-reported survey data. In this study, parents' responses were considered the standard against which students' responses were compared for demographic and family financial items. Both students and parents, however, were assumed to be equally reliable when reporting tuition and fees, room and board, and whether or not the student had ever applied for financial aid.

Comparison by Subgroups

As discussed in chapter 1, previous studies indicate that the quality of responses to surveys may be affected by a variety of student characteristics such as gender, age, race-ethnicity, and socioeconomic status. Table 2.2 lists all the attributes including student, family, and institution characteristics, as well as the method of data collection, that were examined in detail for their associations with the consistency of responses in the NPSAS survey.

Statistical Measures of Correspondence between Responses

Several statistical methods can be used to assess the correspondence between two sets of responses. The most commonly used method is that of statistical correlation, which computes the correlation coefficient between two sets of responses. For variables measured on an interval or ordinal scale such as parents' education and number of siblings, a Pearson's product moment correlation coefficient (r) is employed. For variables on a nominal scale such as race-ethnicity, the statistic called Cramer's V is used.¹⁶ Both r and V can reach a maximum value of 1, and for dichotomous variables, V equals r .

$$V = \sqrt{X^2 / (N \cdot \min(I-1, J-1))}$$

where N = number of observations
 I = number of categories for variable i
 J = number of categories for variable j

Depending on the distribution of the data, other methods of assessment may be more useful. For example, if the data are highly skewed (an example might be if 90 percent of respondents answered "no" to a question and 10 percent answered "yes"), examining the percentage of matched pairs might be a more useful measure of correspondence than the

¹⁵ Correlations for a number of other subgroups including student's age by academic level are listed in appendix C.

¹⁶ M.G. Kendall and A. Stuart, *The Advanced Theory of Statistics, Vol. 2* (New York: MacMillan, 1979).

correlation.¹⁷ Overall, however, it was determined that correlation would be the most illustrative method of measuring the correspondence in the NPSAS data.

Measurement of Bias

Bias may be related to measures of the correspondence between two sets of respondents. Student responses, for example, may correlate with parent responses, yet may systematically under- or over-estimate the value of a specific variable. For example, there may be a strong correlation between the two groups' estimation of parental expectations regarding the student's education, yet students may systematically report lower expectations than do their parents.

In the Feters et al. report on the quality of responses in HS&B, bias was defined as the difference in response means of parents and students:

$$BIAS = \frac{\sum_{i=1}^n x_i}{n_i} - \frac{\sum_{i=1}^n y_i}{n_i}$$

where x_i = the parent response to variable i ,
 y_i = the student response to variable i , and
 n_i = the number of student-parent pairs for variable i .

While a positive bias was associated with overreporting by the student, a negative bias was associated with student underreporting. In this study, the level of bias is reported for all the correlations of variables that are dollar values. Bias is presented in two ways—the mean difference in amount and the percentage difference between the two values.

¹⁷ See appendix B for a discussion and comparison of the correlation coefficient versus the percentage of matched pairs.

Chapter 3

Findings and Results

Student-Institution Comparisons

The first set of comparisons in this section examines the consistency of the student and institution responses concerning demographic information. For this information, both groups of respondents were assumed to be equally reliable in reporting such items. The second set of comparisons concerns family financial items and financial aid items. For reasons discussed in chapter 2, the institutional data for these items were considered the standard against which the student responses were compared.

Demographic Items

Table 3.1 shows the correlation between the student and institution responses to demographic items. As would be expected, the correlations for such variables were quite high, ranging from .75 for race-ethnicity to .97 for age and sex. Overall, the mean correlation was .88 for these variables, well within the range of values found in other studies.

Family Financial Items

The next set of variables, also shown in table 3.1, describes family financial characteristics. The mean correlation for these variables was .63, with the lowest correlation being for parents' income (.33) and the highest for independent student's income (.82). The relatively low correlation for parents' income is consistent with previous studies showing students as relatively inaccurate reporters of their parents' income. Independent students' income, on the other hand, was highly correlated with the institution's record. Independent students, however, were not as accurate in reporting their federal income tax (.60) as they were their income.

Table 3.1—Correlation between student and institution responses to various NPSAS:87 questionnaire items

Variable	Correlation coefficient
<i>Demographic items:</i>	
Age	.97
Sex	.97
Race-ethnicity	.75
Marital status	.81
Type of high school degree	.81
Year of degree	.96
Student residence	.84
Dependency status	.90
	Mean = .88 ¹
<i>Family financial items:²</i>	
Parent's income	.33
Independent student's income	.82
Independent student's federal income tax paid	.60
Number of dependents	.66
	Mean = .63
<i>Student aid-related items: (Y/N)</i>	
Received grant aid	.13
Received work aid	.14
Received loan aid	.17
Received federal aid	.13
	Mean = .14
<i>Student aid-related items: (dollar amount)</i>	
Amount of grant aid	.24
Amount of work aid	.02
Amount of loan aid	.52
Amount of federal aid	.25
Tuition and fees	.59
	Mean = .38

¹ Means are computed using the squared values of the coefficients.

² The amount of students' savings was originally intended to be in the analysis. However, there were several hundred cases that seemed to be outliers where students reported having more than \$100,000 in savings, a 900 percent overestimate of what the institution reported. This appeared to be a significant problem, the reason for which is unclear.

Student Financial Aid Items

The next two groups of variables are correlations for financial aid-related variables. The first group constitutes responses to yes-no questions indicating whether or not a student received a particular type of aid. The second group of variables refers to the amount of aid students received and the amount paid for tuition and fees.

These findings clearly demonstrate NPSAS students were not accurate reporters of whether or not they received a specific type of financial aid. The correlations ranged from .13 to .17. A further examination of the data revealed that institutions reported a student receiving aid much more often than did the student. It is not clear why there is such underreporting by students. As previously discussed, the fact that students need documentation to accurately answer such questions may be a problem. It may also be that students who receive aid from two or more sources may only report one source.

The correlations between students and institutions for the actual amount of aid received were higher than the correlations for the receipt of aid. One exception to this was the amount of work aid received, a correlation of only .02. Unlike the other types of aid, however, the amount of work aid paid to a student may vary during the year. For example, in the beginning of the year a student may be awarded a certain number of hours of work, but the student may actually work fewer hours than were awarded. Even for those students who try to report the amount paid for hours worked, if they were surveyed before the end of the year, they would still be estimating the amount. The institution, on the other hand, had updated employment records at the time of the institution record update.

The correlation for the amount of loan aid received (.52) was the highest among the amounts reported for all the types of aid. This may be due to several factors. Regulations require institutions to spend time counseling a student about student loans and the importance of loan repayment. In addition, the application process for a loan is more involved than it is for a grant, and, thus, a student may be more likely to remember the amount awarded. Finally, in many instances, the loan amounts are awarded in round dollar amounts, making it simpler for students to remember the amount of their loan.

Bias in Student Reporting

Table 3.2 shows the level of bias in student reporting for both the amounts of family financial items and the amount of financial aid awarded. An asterisk indicates that the difference in the average amounts reported between students and institutions is statistically significant. For significant differences, a negative value reflects underreporting of the amount on the part of the students, and a positive value indicates overreporting.

Among the family financial items, students tended to slightly overestimate the amount of federal income tax paid compared to the institution's record. For student financial aid items, however, students consistently underreported the amount of aid received. The differences ranged from almost \$600 for grant aid, a 22 percent difference, to more than \$1,400 for work aid, a 76 percent difference. Among the various types of aid awarded, students were much more accurate in reporting the amounts of loan aid they received than they were other types of aid.

Table 3.2—Bias between student responses and institution data for amounts of family financial items and student financial aid requested in NPSAS:87

Variable	Mean difference	Percentage
<i>Family financial items:</i>		
Parent's income	\$1	0
Student income	118	1
Federal tax paid	67*	7
<i>Student aid items:</i>		
Grant aid	\$-597*	22
Work aid	-1,407*	76
Loan aid	-633*	16
Federal aid	-1,355*	32

*Significant at the 5 % level.

Analysis by Subgroups

In order to examine the consistency of responses between students and institutions for various subgroups, the correlations for the items within each of the four groups of comparisons—demographic, family financial items, receipt of financial aid (y/n), and financial aid amount—were averaged. These average correlations are presented for each subgroup. In addition, the student bias for reporting financial aid-related information is also presented for each subgroup.

Institution-related items.

Table 3.3a shows the correlation for the four groups of variables by institutional type and control. Overall, the demographic variables showed little variation across institutional types. The lowest correlation was .83 for students in private for-profit less-than-4-year institutions, and the highest was .87 for public less than 4-year students.

While not as highly correlated as the demographic variables, the family financial data were also relatively consistent across institutional types, with the possible exception of public less-than-4-year students. The correlation for these students was .58.

Unlike demographic and family financial data, the correlations for receipt of student financial aid, on the other hand, varied across types of institutions, ranging from .08 for public 4-year students to .19 for public less-than-4-year students. Students attending different types of institutions also varied in their accuracy in reporting the amount of aid received. The lowest correlation (.16) was found for students at less-than-4-year private for-profit institutions, while the correlations across the other types of institutions ranged from .23 for students at public less-than-4-year institutions to .35 for students at private 4-year institutions.

The student bias for reporting the amount of financial aid received also tended to vary across institutional types, in particular, between students attending either public 4-year institutions or public less-than-4-year institutions (table 3.3b). Public less-than-4-year students underreported the amount of their grant aid by about 15 percent, compared with 31 percent underreporting for public 4-year students. The reverse was true, however, for the reporting of loan aid, where 4-year students underreported the amount by about 21 percent, compared with 35 percent for public less-than-4-year students.

Table 3.3a—Average correlation between student and institution responses for various groups of NPSAS:87 questionnaire items, by institutional type and control

Institution type	Demographic	Family financial	Student aid (receipt)	Student aid (amount)
Public 4-year	.86	.66	.08	.34

— Sample too small for reliable estimate.

*Significant at the 5% level.

Attendance and dependency status.

Table 3.4a shows the correlations for the four groups of variables by attendance status and dependency status. Whether or not a student attended full time or part time had little relationship with the consistency of their responses in relation to the institution's response. The same was true for dependency status, with the exception of the correlation for family financial items, in which dependent students had a correlation of only .33 compared with .70 for independent students. The relatively low correlation for dependent students was primarily due to their inaccurate reporting of parents' income. Independent students, on the other hand, reported their own income.

Full- and part-time students did tend to differ with respect to their bias in reporting the amount of financial aid they received (table 3.4b). For example, part-time students showed no bias in reporting grant aid, whereas full-time students underestimated the amount they received by about 23 percent or \$654. Part-time students, however, did underreport their federal aid, but only by about 21 percent, compared with about 35 percent for full-time students.

Table 3.4a—Average correlation between student and institution responses for various groups of NPSAS:87 questionnaire items, by attendance and dependency status

	Demographic	Family financial	Student aid (receipt)	Student aid (amount)
Attendance status				
Full time	.85	.63	.13	.23
Part time	.86	.67	.12	.29
Dependency status				
Dependent	.86	.33	.13	.37
Independent	.82	.70	.16	.40

Table 3.4b—Bias between student responses and institution data for amounts of student financial aid requested in NPSAS:87, by attendance and dependency status

	Grant aid		Work aid		Loan aid		Federal aid	
	Mean	Pct	Mean	Pct	Mean	Pct	Mean	Pct
Attendance status								
Full time	\$-654*	23	\$-1,356*	71	\$-649*	4	\$-1,422*	35
Part time	-3	0	-2,577*	91	-448*	3	-626*	21
Dependency status								
Dependent	-549*	33	-1,111*	68	-501*	24	-1,125*	41
Independent	-691*	51	-2,348*	90	-854*	39	-1,720*	54

*Significant at the 5% level.

In general, the bias in reporting the amount of aid they received was greater for independent students than for dependent students. For example, independent students underreported the grant aid they received by about 51 percent compared with 33 percent for dependent students. In part, this result may be due to the fact that independent students received on average relatively larger amounts of aid.

Demographic characteristics.

Table 3.5a shows the correlations between students and institutions for selected demographic characteristics. Unlike previous studies that showed females were somewhat more accurate reporters of items in education surveys than males, no such differences were found for the items examined in the NPSAS survey. Males and females exhibited about the same level of consistency regardless of the item. The same was true for race-ethnicity, with the possible exception of family financial items. For these items, white students had the lowest correlation (.57), while Asian students had the highest (.70).

Table 3.5a—Average correlation between student and institution responses for various groups of NPSAS:87 questionnaire items, by selected student characteristics

	Demographics*	Family financial items	Student aid (receipt)	Student aid (amount)

— Correlation not reported because row variable was one of only 3 items for this group.

* Average correlation of demographic items other than row variable.

No obvious differences in the consistency of reporting demographic information were found for students at various income levels. While students in the highest income levels had the highest correlations (.91 for dependent students' parents' income of \$100,000 or more and .83 for independent students' income of \$20,000 or more), the level of consistency was quite high across all levels of income. There were also no apparent differences for the other two groups of items—student aid receipt and student aid amount—in relation to income level.

The level of bias students exhibited in reporting amounts of financial aid received is shown in table 3.5b according to demographic subgroups. As was true for the correlations, no gender differences in the level of reporting bias were found. Some variations in bias, however, were observed for race-ethnicity and for income level. For example, Asian students showed no bias in reporting the amount of loan aid received, and a relatively low level of bias for reporting grant aid (23 percent underreporting). White students also had a relatively low level of bias in reporting grant aid (17 percent underreporting) compared with other racial-ethnic groups (bias ranging from 23 percent to 56 percent underreporting).

There was no general pattern to the variation of bias observed for students at various income levels, although students in the lowest income levels tended to have the greatest bias in reporting amounts of financial aid received. These students, however, are also more likely to receive higher awards than higher income students and, thus, the possibility of biased reporting is higher for low-income students.

Table 3.5b—Bias between student responses and institution data for amounts of student financial aid received in NPSAS:87, by selected student characteristics

*Significant at the 5% level.

Parent-Institution Comparisons

This section examines the consistency between dependent students' parents and institution responses to items related to parents' income, federal taxes paid, tuition and fees, number of dependents, and number of dependents in college. Due to the verification required to document the financial need of students applying for financial aid, the institution records were assumed to be more accurate than the parent responses for these comparisons.

The correlations between parent and institution responses for number of dependents, adjusted gross income, and federal taxes paid were relatively high, ranging from .76 for federal taxes paid to .83 for adjusted gross income (table 3.6). The somewhat lower correlation for the number of dependents in college (.65) could possibly be due to the different ways in which the question was asked of the institution and the parents. Parents were asked about their dependents in two parts. Part one asked how many people will

you and your spouse support between September 1986 and May 1987? Include yourself, your spouse, other children, and any others receiving more than half their support during that period. Do **not** include your child who is in our survey.

Part two then asked:

Of these, how many have been enrolled in postsecondary school....Please include your spouse, if applicable, but do **not** include yourself.¹⁸

Thus, the first part of the question excludes the student in the survey. The second part should also exclude the participating student, but the responding parents are not reminded of this and, in addition, the second question also excludes the responding parent if he or she is enrolled in postsecondary education. The institution, on the other hand, was asked for the "total number in household in college." By subtracting 1 from this number, it should correspond to the parents' response unless the responding parent was also enrolled in postsecondary education. Thus, the complexity of the question asked of the parent may have contributed to the lower correspondence between parent and institution responses.

Table 3.6—Correlation and the level of bias between parent and institution responses for various NPSAS:87 items

Variable	Correlation	Bias (mean difference in amount)	Percent
Number of dependents	.79	0	1
Number in college	.65	0	26
Adjusted gross income	.83	\$255	1
Tuition and fees	.65	1,604*	63
Federal taxes paid	.76	365*	10

*Significant at the 5% level.

¹⁸ NPSAS:87 *Methodology Report*, Appendix A, Parent Questionnaire, 11.

It was less surprising to see the lower correlation between parents and institution for the amount of tuition and fees. Unless they directly paid the tuition and fees or had the documentation in hand, one would be less inclined to think that the responding parent could recall the exact amount of tuition and fees paid to the school for the 1986-87 school year. The same is true, to a lesser extent, for the amount of federal income taxes paid.

The only systematic biases observed for parent responses when compared to the institution data were for tuition and fees and the amount of federal taxes paid. In general, parents considerably overestimated (by about 63 percent) the amount of tuition and fees paid to the institution. Parents' bias in overreporting their federal taxes, though statistically significant, was much lower (about 10 percent) than for tuition and fees.

Analysis by Subgroup

Correlations between parents and institutions for number of dependents, adjusted gross income, federal income taxes, and tuition and fees are presented in table 3.7 for selected subgroups. When examining these differences, however, it should be remembered that the parent survey was plagued by substantial item non-response. This was especially true for adjusted gross income (35 percent missing) and federal income tax paid (40 percent missing). Thus, when these responses are broken down into subgroups, the correlations often represent a relatively small number of respondents.¹⁹

¹⁹ While the total Ns for each item are listed in table 2.1, the individual cell sizes for the categories in table 3.7 can be found in appendix B. It is not uncommon for some cell sizes, especially for adjusted gross income and federal taxes paid, to be under 100. However, if the cell size dropped below 30, the correlation is not shown.

— Item included in correlation.

— Sample too small for reliable estimate.

In general, the correlations between parent and institution responses tended to be lower for low-income parents, especially those with incomes under \$12,000. No other obvious patterns emerged, though some singular differences were notable. For example, parents of black students tended to be less accurate than other parents in reporting number of dependents (.60) and tuition and fees (.41), while parents of Hispanic students appeared to be less accurate reporters of adjusted gross income (.45). On the other hand, parents of white students tended to be less accurate in reporting federal income taxes paid than parents of minority students (.75 compared with .87 or higher).

With regard to the amount of tuition and fees paid, the correlation between parents of students in public less-than-4-year institutions and the institution was especially low (.16). This is not surprising, however, since students in public less-than-4-year institutions often attend school part-time. Therefore, their tuition and fees would be related to the number of courses or units taken rather than a flat fee for full-time attendance. Related to this was the lower correlation for tuition and fees observed for parents of part-time students (.46) relative to parents of full-time students (.64).

Though the telephone survey was very successful in surveying the considerable number of parents who did not respond to the mailed survey, this method of data collection did not seem to be associated with more accurate responses to the questionnaire items examined in this analysis. With the possible exception of adjusted gross income, the correlations for each method of data collection were relatively close. In the case of income data, where the correlation for the parents who responded by mail was .88 compared with .69 for those who were interviewed by telephone, it is possible that parents who responded by mail took the time to refer to their tax forms to report their adjusted gross income, while the parents surveyed by phone may have relied more on their memory.

Bias.

It is clear from the bias estimates shown in table 3.8 that, regardless of subgroup attributes, parents consistently overestimated the amount of tuition and fees paid. It is probable that they included other expenses in the amount they reported. This would be especially true for parents who did not directly pay tuition and fees to the institution, but provided a certain amount of money to the participating student, for tuition and fees as well as other expenses such as books, room and board, transportation, and so on.

There was no obvious systematic bias for the subgroups examined between parent and institution responses for adjusted gross income or for federal taxes paid. Overall, there was a slight overestimate of federal taxes paid (about 10 percent) for parents participating in either the mail or the telephone survey.

Parent-Student Comparisons

The third and final analysis compared the consistency of student and parent responses to questions concerning parents' highest level of education, family financial characteristics, education expenses, and parents' contributions toward education expenses. Two of the family financial items represent characteristics that determine whether or not a student is financially dependent. These items ask if the student was claimed as an exemption for tax purposes and how many weeks the student lived in the family home in 1986. For this analysis, it was assumed that parents would be more accurate than students in reporting parents' highest level of education and items concerning parents' contributions to the participating students' education. Students, on the other hand, were presumed to be more accurate reporters of their educational expenses such as tuition and fees and room and board.

The correlations between student and parent responses for parents' highest level of education were .63 for mother's education and .69 for father's education (table 3.9). These correlations are somewhat lower than one might expect for factual demographic characteristics. However, the question asked not only for the level of education (such as less than high school, high school, vocational training, college, and so on) but the number of years of postsecondary training for parents who had not earned a baccalaureate or advanced degree. While students' may easily know the general level of their parents' education, they may not know much detail about the length of training for parents who did not obtain a college degree.

Table 3.9—Correlation between student and parent responses to various NPSAS:87 questionnaire items

Variable	Correlation
<i>Demographics</i>	
Mother's education	.63
Father's education	.69
<i>Family financial items</i>	
Parents' income (categorical)	.27
Number of weeks lived at home	.87
Claimed as an exemption	.36
<i>School expenses</i>	
Tuition and fees	.64
Room and board	.20
Ever apply for aid	.41
<i>Parent financial contributions</i>	
Amount parents lent to student for education	.17
Amount parents contributed (non-loan)	.54

As was true for the correlation between student and institution responses regarding parents' income, the correlation between student and parent responses for the same item was low (.27). Similarly, students did not necessarily know whether or not their parents had claimed them as an exemption on their 1986 tax return (.36). This again reinforces the idea that students often do not know their parents' financial status. The only correlation that was high among the family financial items examined in this analysis was for the number of weeks students lived in the family home (.87).

While students and parents had moderate agreement for the amount of tuition and fees paid (.64), they had relatively poor agreement for the cost of room and board (.20). However, parents who did not pay the institution directly for tuition and fees and other expenses, but who provided the students with a certain amount of money to cover expenses, may not know exactly how that money was distributed. The relatively low correlation for whether or not the student had applied for financial aid (.41) is more surprising, the reasons for which are unclear. It would seem likely that parents would know whether or not their child had applied for financial aid, especially for parents of financially dependent students who would have to provide the institution with information regarding their financial status if the student applied for financial aid.²⁰

The pattern of parent and student responses regarding how much money parents either contributed or lent to the student is notable. Overall agreement was quite low for the amount of money parents lent the student (.17), while agreement for the non-loan amount contributed was higher (.54). It seems that students were more likely to underreport the amount of money their parents lent them by about 41 percent, and overreport the amount of money their parents contributed (not loans) to their education, by about 19 percent (table 3.10).

Table 3.10—Bias between student and parent responses for school expenses and parent loans and contributions to educational expenses

Variable	Mean difference	Percent
Tuition and fees	\$-1,427*	38
Room and board	-771*	75
Amount parents lent to student	-248*	41
Amount parents contributed	930*	19

*Significant at the 5% level.

Analysis by Subgroup

Correlations between students and parents for specific subgroups concerning the financial items included in this analysis are shown in table 3.11. In general, the correlation between students and parents for those enrolled in public less-than-4-year institutions was lower than for students who attended other institutions. As discussed previously, however, a greater percentage of part-time students attend public less-than-4-year institutions, and, therefore, expenses would generally be more variable than expenses for full-time students. In contrast, there was somewhat greater agreement between students and parents among those attending private not-for-profit and public 4-year institutions as well as for students attending private for-profit less-than-4-year institutions. These institutions primarily have full-time students with a standard rate for tuition and fees.

²⁰ While it was true that the correlation between students and parents was lower for independent students (.33), the correlation between dependent students and their parents was only .49 (data shown in appendix C).

Table 3.11—Correlation between student and parent responses for education expenses, parent loans, and parent contributions, by selected subgroups

\$15,000–20,000	.47	-.08	—	—
\$20,000 and over	.42	.12	—	—

— Sample too small for reliable estimate.

Full-time students tended to have greater agreement with their parents regarding the amount of tuition and fees and the amount their parents contributed to their education expenses than did part-time students. Part-time students, on the other hand, tended to have greater agreement with their parents concerning the amount of money their parents lent them for education expenses.

Agreement between parents and students according to income level appeared highly variable. With regard to tuition and fees, however, agreement tended to be greater for middle-income groups (e.g., parents earning \$24,000 to \$50,000 and students earning \$10,000 to \$15,000) than they were for lower or higher income groups.

Bias.

Table 3.12 shows the amount of bias between students and parents among various subgroups as a percentage of the parent response for each variable. Regardless of subgroup, on average, students reported lower amounts than parents for tuition and fees, amount paid for room and board, and the amount of money parents lent to students. This was especially true for room and board, where students underreported parents from 48 percent to 86 percent. Bias for the non-loan amount of money parents contributed to students' education was in the opposite direction. However, students generally reported greater amounts contributed than did their parents.

Table 3.12—Bias between student and parent responses for education expenses, parent loans, and parent contributions as a percentage of parent response, by selected subgroups

Chapter 4

Comparison of NPSAS:87 and CPS Data

Even though NPSAS is the most comprehensive survey of postsecondary students and their finances, it is not the only survey concerning postsecondary education. Other large surveys do include information on postsecondary students, but often as a subset of a larger population of students. For example, High School and Beyond (HS&B) is a longitudinal survey of 1980 high school seniors and sophomores that includes their postsecondary experiences in follow-up surveys. Another postsecondary education survey is the Integrated Postsecondary Education Data System (IPEDS). However, IPEDS is an institutional-based survey in which institutions report on revenues and expenditures and on enrollment of various types of students. In addition, there are surveys of the general population that contain information on students in postsecondary education. The most comprehensive of these surveys are the Current Population Survey (CPS) and the Survey of Income and Program Participation (SIPP), both conducted by the Bureau of the Census, which use stratified random samples of U.S. households and provide information on the demographics and economics of families.

In this analysis demographic characteristics of CPS participants were compared with those of the NPSAS sample. CPS is a survey of about 60,000 households that is currently conducted monthly in order to gather information on the demographic and economic characteristics of a representative sample of the U.S. population. Each CPS has a slightly different emphasis. Because the October survey focuses on education, the October 1985 CPS was selected for comparison with the NPSAS sample.²¹

Although there are certain similarities between the two surveys, they were conducted in entirely different ways. CPS used households as its primary unit of analysis and collected data on all residents in a given household. NPSAS, on the other hand is a representative sample of students who were enrolled in postsecondary education in the fall of 1986. Thus, in NPSAS, individual students were the unit of analysis, rather than students within a household. It is instructive, however, to compare the samples from these two surveys because both are used widely in postsecondary education research. Until NPSAS, CPS was one of the few surveys that could be used to examine the demographic characteristics of postsecondary education students.

For this analysis, comparisons were made between the NPSAS sample of students who were under age 35 and the CPS subsample of households with postsecondary students.²² The percentage distributions of the two samples were compared for student and family characteristics including sex, age, race, marital status, and family income. Although some education-related questions were asked in the CPS, they are not directly comparable to the items asked in the NPSAS survey and are not compared in this analysis.

²¹ The comparisons made in this chapter differ from those in previous chapters in that they use weighted data rather than unweighted data.

²² CPS data presents postsecondary data for college students 16 through 34 years old. Therefore, NPSAS students who were over 34 years old were removed from the comparison.

Given the differences in the way in which the CPS and NPSAS surveys were conducted, the distributions of demographic characteristics were remarkably similar (table 4.1). The only apparent differences were that NPSAS tended to have a slightly higher percentage of females, and the students were somewhat more likely to be married. For example, among male students, 19 percent of those in the NPSAS survey were married, compared with 14 percent from the CPS. Similarly, 22 percent of NPSAS female students were married, compared with 16 percent of CPS students. Among students under 35 years old, the age distribution of NPSAS and CPS students was virtually the same for the two surveys. Thus, this does not provide an explanation for the difference in the marital status distributions between the two samples.

Table 4.1—Percentage of students in the October 1985 CPS and NPSAS:87, by gender, age, gender by age, race, and marital status by gender

<u>Gender</u>		<u>Male</u>	<u>Female</u>	
CPS		49.5	50.5

Table 4.2 shows the distribution of family income for the two samples. For this comparison, the CPS sample is composed of households with primary family members aged 18-24 who were attending college. The NPSAS sample is limited to students who were identified as financially dependent on their parents (the only students for which family income is reported). The distribution of family income between the two samples appeared to differ markedly, especially for the lowest and highest income ranges. For example, a greater percentage of NPSAS students were from families with annual incomes of less than \$10,000, while more than twice as many CPS students were from families whose annual income was \$50,000 or more. One possible explanation for this difference is the fact that the CPS sample included students who were living in their family household. Thus, students who were living away from home (for example, those living in campus housing) would not be included in the sample. Furthermore, CPS students' financial dependency status was not determined. NPSAS, on the other hand, is representative of students rather than households, regardless of their living arrangements.

Table 4.2—Percentage of students in the October 1985 CPS and NPSAS:87, by family income

Family income*	Less than \$10,000	\$10,000- 19,999	\$20,000- 29,999	\$30,000- 39,999	\$40,000- 49,999	\$50,000 or more

Chapter 5

Summary and Conclusions

This report examined the consistency of responses in the NPSAS:87 survey among the three groups of respondents—students, parents, and institutions. Three sets of comparisons were made: between students and institutions, between parents and institutions, and between students and parents. In addition to measuring the consistency of responses, the level of bias in reporting dollar amounts such as financial aid, education expenses, and family income was also examined. Except for the comparison between students and institutions for demographic items, comparisons involving institutions were limited to students who received financial aid.

While no one source of data was always considered the “standard” against which the other sources were compared, the institution was often presumed to be the most reliable source. This was because many of the items examined were related to financial aid, and information provided to the institution on financial aid applications must be verifiable. Furthermore, the institution record was updated to take into account changes in financial aid status that might have occurred over the year.

The results of the analysis varied according to the items being compared. As might be expected, the correlations between students and institutions for demographic items were relatively high, with a mean correlation of .88. However, the most compelling results were those showing very little agreement between students and institutions with regard to the receipt and amount of financial aid awarded. The mean correlation for items in which students were asked whether or not they received specific kinds of financial aid was only .14. The correlations between students and institutions for items concerning the actual amounts received were higher (.38); however, agreement was still relatively low. Students tended to have the strongest agreement with institutions for the amount of loan aid received (.52), and the weakest for the amount work aid received (.02).

In addition to the poor correspondence between students and institutions for financial aid items, students tended to systematically underreport the amounts of aid they received. Underestimates by the students relative to the institution records ranged from 16 percent for loan aid to 76 percent for work aid. This underreporting was observed regardless of the type of institution attended and student characteristics.

Students had moderate agreement with institutions regarding family financial items (mean correlation of .63). Among these items, the highest correlation was for independent student's income (.82), and the lowest was for parents' income (.33). The latter result is consistent with earlier studies showing students as relatively unreliable predictors of parents' income.

With respect to the comparisons involving parents, it should be remembered that the parents' survey had a relatively high nonresponse rate, both to the survey (42 percent) and for specific survey items among those who did respond. This was especially true for reporting adjusted gross income and the amount of federal income tax paid. However, among parents who did respond, their agreement with the institutions was quite high for their adjusted gross income (.83). Agreement was lowest for the amount of tuition and fees paid (.65), while agreement for

the parents' federal income taxes fell in between these two ranges (.76).²³ With respect to bias, parents consistently overestimated the amount of tuition and fees paid relative to what the institution reported.

In the final comparison, that between students and their parents, students had relatively good agreement with their parents regarding parents' highest education (.63 and .69, respectively, for mother's and father's highest education), although this agreement was not as high as one might expect for such a factual item. However, part of the question required students to know the number of years of postsecondary training for parents who had less than a bachelor's degree, a detail students would be less likely to know than the general level of their parents' education.

Students had moderate agreement with their parents with regard to the amount tuition and fees (.64) paid. However, as was true with the student-institution comparisons, there was poor correspondence between students and parents for family financial items such as parents' income (.27) and the amount of parental loans to students for education expenses (.17). Agreement between students and parents for the amount of non-loan contributions made by parents, however, was somewhat higher (.54). It is interesting to note the bias observed in student reporting relative to their parents. The amount of parental loans was consistently underreported by the students, while the amount of non-loan contributions was consistently overreported.

The results of this study indicate that NPSAS students were reliable reporters of general demographic information, but a poor source of information regarding the receipt and amount of financial aid awarded. Similarly, students had poor agreement with parents when reporting on family financial items. However, if the importance of the student survey in NPSAS is to obtain financial information on independent students who do not receive financial aid, among the few items only independent students were asked (for student income and number of dependents), agreement with the institution was relatively high. Similarly, if the importance of the parent survey is to obtain financial information on dependent students who do not receive financial aid, among the parents included in this analysis (parents of dependent students who received financial aid), the correspondence between parents and institutions was moderately high for family financial characteristics.

²³ The correlation between parents and institutions for the number of dependents in college was also .65; however, there was quite a difference in the way the question was posed to the parents and the institutions.

Appendix A

Methodology and Technical Notes

Source of Data

Estimates in all tables of this report are based on the 1986-87 National Postsecondary Student Aid Study (NPSAS). The 1986-87 survey was designed to collect financial aid and financial support information on a national sample of postsecondary students enrolled in the fall of 1986 at all academic levels and all types of institutions. Besides financial aid information, the data set also contains information on the students' socioeconomic and demographic characteristics and on their academic backgrounds, programs, and objectives. NPSAS includes three groups of postsecondary students: undergraduates, graduates, and first-professionals. Only the undergraduates were used for this analysis.

NPSAS used a three-stage sample design that involved clustering of units at the first stage and stratification of sampling units at each stage. The original sample for the 1986-87 NPSAS data collection consisted of 1,353 postsecondary institutions, clustered by geographical areas and stratified according to the highest program level (i.e., 4-year doctoral-granting, 4-year non-doctoral-granting, 2-year, or less-than-2-year) and institutional control (i.e., public, private not-for-profit, or private for-profit). The final institutional sample was reduced to 1,074 after some institutions were found to be ineligible and others refused to participate. The institutional response rate, weighted by the probability of selection and enrollment, was about 95 percent.

A stratified sample of approximately 60,000 students was then drawn from the October 1986 records of the institutions in the institutional sample. Students were stratified by level (undergraduate, graduate, or first-professional). Different sampling rates were used for each level. For each student in the sample, efforts were made to collect registration and financial aid records from the institution. All student record information collected in the fall term was updated during the spring of 1987. This information was supplemented by mail and telephone survey information collected directly from students during the spring of 1987. In total, the 1986-87 NPSAS record and student questionnaire file contains information on 43,176 students (34,544 undergraduates and 8,632 other). The overall response rate for students was 67 percent.

A Parent Questionnaire was mailed to the parents or guardians of a subsample of students chosen for participation in the 1986-87 NPSAS data collection. The purpose of this survey was to obtain detailed information on the family and economic characteristics of dependent students who did not receive financial aid. In keeping with this purpose, parents of financially independent students who were over 25 years of age were omitted from the sample. The overall response rate for this questionnaire was about 58 percent.

The majority of the analyses conducted in this report were based on unweighted data from the NPSAS survey. Only the NPSAS—CPS comparisons were based on weighted data. For a discussion of the weighting procedures used to weight the NPSAS survey, see the *Methodology Report for the National Postsecondary Student Aid Study, 1987* (Contractor Report, prepared for the National Center for Education Statistics, NCES90-309, March, 1990).

For more information on the NPSAS survey, consult the *National Postsecondary Student Aid Study Updated Record and Student Questionnaire (1987) Data File User's Manual* (Longitudinal Studies Branch, Postsecondary Education Statistics Division, Washington, D.C.: National Center for Education Statistics, U.S. Department of Education, March 1989) and the

National Postsecondary Student Aid Study Parent Survey Supplement Data File, Data File User's Manual (Westat, Inc., Washington, D.C., a contractor report prepared for the National Center of Education Statistics, U.S. Department of Education, August, 1988).

Appendix B

Alternative Measures of Correspondence

Earlier sections of this report discussed the fact that the correlation coefficient is not necessarily a reliable indicator of the relationship between variables when marginal distributions are not normally distributed. Skewed distributions can produce significantly lower correlation coefficients than would be expected based on the actual number of corresponding responses, or matches. Table B.1 addresses this issue by presenting two alternative measures of correspondence. Presented in the table are the percentage of matches and the relative bias, in addition to the Cramer's V, for all demographic categorical variables employed in this quality of response analysis report. In addition, the mean response values are displayed. The mean difference or bias value is calculated from the difference between these two values.

Theoretically, there need not be any association between the percent of matches and the correlation coefficient given the influence of distributions of each variable. Therefore, it is quite possible for the majority of observation pairs to have similar responses (high match rate) but a very low correlation. The magnitude of the relative bias may also be independent of the size of the correlation coefficient since it is possible to have a high correlation and either a high or low relative bias. We would expect, however, to find a negative relationship between the match rate and relative bias given that a high proportion of matches should produce a smaller difference between the two means. This association may not be evident, however, when large differences between the match rate and correlation coefficient indicate a highly skewed distribution. In this case, the high match rate and highly skewed distribution would tend to inflate the magnitude of the relative bias in proportion to the difference between the match rate and correlation coefficient.

Table B.1 shows the percentage of identical student-institution responses for all categorical demographic variables in the quality of responses analysis. Demographic variables indexing student age and year of high school degree are not included since these variables are not categorical. It is important to recognize here that the variables listed, in addition to being categorical, are also only measured at the nominal level and therefore the reader should be very careful when attempting to interpret the index of relative bias presented in the table. Measures of central tendency, and statistics based upon them, cannot be meaningfully interpreted when the data do not achieve at least an ordinal or interval level of measurement. The mean value for race-ethnicity, for example, provides no useful information about the average ethnic makeup of the NPSAS sample. Corresponding bias indices based on the means are consequently meaningless as well.

Table B.1—Comparison of measures of correspondence for all categorical demographic variables.

Variable	Percent Match	Cramer's V
Gender	98.6	.97
Race—ethnicity	94.6	.75
Marital status	96.9	.81
High school degree	94.6	.81
Residence status	89.7	.84
Dependency status	95.3	.90

Given the factual nature of the demographic items such as gender or race-ethnicity it is not surprising that the match rates appear to correspond to the Cramer's V statistic quite well. For demographic items there is no obvious reason to expect a systematic reporting bias to influence the marginal distributions for these variables which could increase the disparity between the percentage of matches and Pearson r or Cramer's V statistic. It can be seen that the percentage of identical responses for each variable is consistently somewhat higher than is indicated by the associated Cramer's V statistic. Thus it appears that the measure of association employed in this analysis may slightly underestimate the correspondence between student and institution responses to the class of demographic items that are both categorical and nominal.

The difference between the match rate and Cramer's V statistic is particularly pronounced for the student race-ethnicity item. Further examination of the frequency marginals and the student-institution crosstabulation for this item shows a clear pattern of misclassification of Hispanic responses. For example, about 3 percent of students who classified themselves as Hispanic were classified as white (non Hispanic) by their institution. In this case, then, it seems as if the confusion surrounding one level of the variable class functioned to depress the Cramer's V statistic by skewing the distribution even though over 95 percent of all student-institution responses were in complete agreement.

The financial variables present a similar situation to that of the demographic variables. Table B.2 shows the alternative measures for the financial variables. The disparity between the correlation and match rate is particularly evident in the binary student-institution comparison variables—grants, work, loans, and taxes. Looking at the correlation coefficient alone belies the fact that well over half of student responses were identical to the institutional response for the given variables. Reports of work-study aid received (yes or no) show a correlation of only .14 even though over three-fourths of the students were in complete agreement with the institution response. The large disparity between the match rates and corresponding correlation coefficients for these variables may also account for the relatively large bias figures associated with these variables.

Similar patterns are found in the parent-student comparisons, although the pattern is less pronounced. Student responses to the parent contribution variable, for example, correlated only .56 with their parent's response to this same variable, even though over 80 percent of the responses were identical.

This analysis shows that there is no single measure of correspondence that fully captures the relationship between two variables. Many measures are consistent with one another, but each one may give a slightly different measure of the relationship.

Table B.2—Comparisons of measures of correspondence for financial variables

	Percent of Matches	Correla- tion	Relative Bias	Student Mean Value	Parent Mean Value	Inst. Mean Value

Appendix C

Statistical Tables

List of Variables in Appendix C

Student—Institutional Comparisons

Age	Age of student in years
Gender	Gender of the student
Race/ethnicity	Race of the student
Marital status	Marital status of the student
High school degree	Type of high school degree obtained by the student
Year of high school degree	Year in which high school degree was obtained
Student residence	Local residence of student while in school (on campus, off campus, with parents)
Dependency status	Dependency status of the student
Grant aid received	Receipt of grant aid (y/n)
Grant aid amount	Amount of grant aid received
Work aid received	Receipt of work aid (y/n)
Work aid amount	Amount of work aid received
Loan aid received	Receipt of loan aid (y/n)
Loan aid amount	Amount of loan aid received
Federal aid received	Receipt of federal aid (y/n)
Federal aid amount	Amount of federal aid received
Parent's income	Amount of dependent student's parents' income in 1985
Number of dependents	Number of dependents of independent students
Amount of savings	Amount of savings for independent students
Student's income	Amount of independent student's total income in 1985
Federal taxes	Amount of federal taxes paid by independent students in 1985
Tuition	Cost of tuition and fees

Parent—Institutional Comparisons

Number of dependents	Number of dependents other than student in survey
Number in college	Number of dependents in college other than the student in survey
Adjusted gross income	Amount of adjusted gross income in 1985
Tuition	Cost of tuition and fees of the student
Parent's federal tax	Amount parents paid in federal taxes in 1985

Parent—Student Comparisons

Tuition	Cost of tuition and fees of the student
Room and board	Cost room and board
Ever apply for aid	Student or parents apply for financial aid (y/n)
Parent loans to student	Amount loaned by parents to student
Parent's contribution	Parent contribute to student's educational costs (y/n)
Amt of parent's contribution	Amount of parents' contribution toward educational costs
Mother's education	Level of educational attainment by student's mother/guardian
Father's education	Level of educational attainment by student's father/guardian
Number of weeks at home	Number of weeks student was at home in 1985
Claim as exemption	Parents claim student as an exemption in 1985 (y/n)
Parent's income (categorical)	Category of parents' total income in 1985 Less than \$11,000 \$11,000 - 16,999 \$17,000 - 22,999 \$23,000 - 29,999 \$30,000 - 49,999 \$50,000 or more

Appendix D

Data Items With Differences in Wording Between Respondents

Student-Institution Records

Tuition and fees

- Institution: What were the total tuition and required fees charged prior to any discounts or allowances (for the fall term or program specific charges, whichever is appropriate)?
- Student: How much did you pay to the school you were attending? For tuition? For fees?

Receive federal aid

- Institution: Program-by-program specific questions. For example, Pell Grants.
- Student: Source of award by type of award. For example, Grants/Scholarships-Federal.

Amount of federal aid

- Institution: Program-by-program amounts and length of award in months.
- Student: Amount of award by source of award by type of award.
Amounts for entire school year.

Parents' income

- Institution: Parent's IRS adjusted gross income
- Student: In studies such as this, families sometimes are divided into groups according to how much money they make in a year. Please indicate the group which comes closest to the amount of TOTAL family income your parents/guardians make or made in a year.

\$10,999 or less
\$10,000 - 16,999
\$17,000 - 22,999
\$23,000 - 29,999
\$30,000 - 49,999
\$50,000 or more
Don't know

Number of dependents

Institution: Total number of exemptions

Student: How many dependents do you have for whom you provide at least half of their support, excluding yourself?

Savings (net assets)

Institution: Student's (and spouse's) cash, savings, checking account. Student's (and spouses's) assets (current worth less amount owed)--Home equity, other real estate and investments, and business/farm.

Student: At the end of 1986, what were your and your spouse's total assets (fair market value) including savings, checking accounts, cash, stocks, home, business, farm, etc.? What was your and your spouse's total debt, excluding educational loans (including debts on house, other real estate, farm, or business)?

Parents-Institution

Number of dependents

Institution: Total number in household in 1986-87?

Parents: How many people will you and your spouse support between September 1987 and May 1987? Include yourself, your spouse, other children, and any others receiving more than half their support during that period from you and your spouse.

Number in colleges enrolled half-time

Institution: Total number in household in college at least half-time in 1986-87?

Parents: Of these, how many have been or will be enrolled in postsecondary school (in college, university, trade or business school) at any time during September 1986 through May 1987? Please include your spouse, if applicable, but do not include yourself. Will you be in postsecondary school at any point during the period? Of the total number of persons in your family who were attending a postsecondary school during this period (including yourself, but not your child in this survey), how many took more than one course a term or attended for more than 20 hours per week?

Tuition and fees

Institution: What were the total tuition and fees charged prior to any discounts or allowances (for the fall term or program-specific charges, whichever is appropriate)?

Parents: How much was paid to the school for tuition and fees from September 1986 through May 1987?

Parents' taxable income

Institution: Income earned from work--father, mother.

Parents: What was you and your spouse's 1985 taxable federal income?

Parents-Students

Parents' income

Parents: In calendar year 1986, what was you and your spouse's total income (before withholding) from all jobs?

Student: In studies such as this, families sometimes are divided into groups according to how much money they make in a year. Please indicate the group which comes closest to the amount of TOTAL family income your parents/guardians make or made in a year.

\$10,999 or less
